More transportation options such as transit, walking and biking are good for the environment, economy, and social equity. Yet, the system we currently have revolves around car dependence, bolstered by outdated policies and industry lobbying.

New UCS analysis finds that:

- A system with improved transportation options and reduced driving could save up to \$201 billion in energy infrastructure and \$128 billion in public health costs through 2050, presenting a more effective climate solution than the current car-dependent model.
- The auto and oil industries have a vested interest in car dependence, currently receiving more than 75 percent of public and private transportation spending and have lobbied for decades to prioritize cars over a more complete and affordable set of transportation options.

- Science-based policies that prioritize more transportation choices align with community-based solutions where local advocates have long fought for a transportation system that prioritizes people over industry interests.
