

The analysis of FARS data showed that:

- Approximately 84 fatal crashes occurred per year during the 1982-1992 time period involving a right-turning vehicle at an intersection where RTOR is permitted. During this same time period there were 485,104 fatalities. Thus, less than 0.2 percent of all fatalities involved a right-turning vehicle maneuver at an intersection where RTOR is permitted. FARS, however, does not discern whether the traffic signal indication was red. Therefore, the actual number of fatal RTOR crashes is somewhere between zero and 84 and may be closer to zero than 84.
- Slightly less than half of the fatal RTOR crashes involve a pedestrian (44 percent), 10 percent a bicyclist and in 33 percent one vehicle striking another vehicle.

The results of the data analysis from the four state crash files suggest the following:

- Right-Turn-On-Red (RTOR) crashes represent a very small proportion of the total number of traffic crashes in the four states (0.05 percent).
